Learn More.Extensive research library from industry leaders.The present invention relates to an overhead door having a shaft between the door leaf and the door frame for transmitting a force from the door leaf to the door frame, and including a drum which is connected to the shaft, a drive shaft which can be driven in rotation and is connected to the drum, and a plurality of torsion springs which are arranged on the drum and are disposed between the drum and the shaft and between the shaft and the door frame, and which are each in the form of a helical spring and which bear against the shaft and against the door frame, respectively, and which cooperate with the drum to support the door. Overhead doors have been in existence for a long time and have proved their worth when it comes to achieving certain advantages. For example, they facilitate entry into a building in the case of high rise buildings and they keep out cold air in winter or hot air in summer. In the latter case, it is generally endeavored to achieve a seal, in which case the overhead door has a long sealing strip which is made of rubber or plastic and is applied to the door frame. A drawback of such a sealing arrangement is that it usually can only be applied to a door which has a straight profile. In the case of profile-shaped doors such as, for example, a double door, the sealing strip is also either too narrow or too short to be applied to the door frame, or in the latter case, in the case of a relatively long sealing strip, the strip may be wound around the door frame with great difficulty. In order to overcome these drawbacks, it has already been proposed to provide overhead doors with a mounting means which engages behind the door frame and which has a support which is disposed between the mounting means and the door frame and which bears against the door frame, and to install the torsion springs in this support. In this arrangement, the support can be positioned in the manner of 82157476af
